Python Keywords and Identifiers

programiz.com/python-programming/keywords-identifier

In this tutorial, you will learn about keywords (reserved words in Python) and identifiers (names given to variables, functions, etc.).

Python Keywords

Keywords are the reserved words in Python.

We cannot use a keyword as a <u>variable</u> name, <u>function</u> name or any other identifier. They are used to define the syntax and structure of the Python language.

In Python, keywords are case sensitive.

There are 33 keywords in Python 3.7. This number can vary slightly over the course of time.

All the keywords except True, False and None are in lowercase and they must be written as they are. The list of all the keywords is given below.

False	await	else	import	pass
None	break	except	in	raise
True	class	finally	is	return
and	continue	for	lambda	try
as	def	from	nonlocal	while
assert	del	global	not	with
async	elif	if	or	yield

Looking at all the keywords at once and trying to figure out what they mean might be overwhelming.

If you want to have an overview, here is the complete <u>list of all the keywords</u> with examples.

Python Identifiers

An identifier is a name given to entities like class, functions, variables, etc. It helps to differentiate one entity from another.

Rules for writing identifiers

- Identifiers can be a combination of letters in lowercase (a to z) or uppercase (A to Z) or digits (o to 9) or an underscore _ . Names like myClass , var_1 and print_this_to_screen , all are valid example.
- 2. An identifier cannot start with a digit. 1 variable is invalid, but variable is a valid name.
- 3. Keywords cannot be used as identifiers.

```
global = 1
```

Output

4. We cannot use special symbols like !, @, #, \$, % etc. in our identifier.

```
a@ = 0
```

Output

```
File "<interactive input>", line 1
    a@ = 0
         ^
SyntaxError: invalid syntax
```

5. An identifier can be of any length.

Things to Remember

Python is a case-sensitive language. This means, Variable and variable are not the same.

Always give the identifiers a name that makes sense. While c = 10 is a valid name, writing count = 10 would make more sense, and it would be easier to figure out what it represents when you look at your code after a long gap.

Multiple words can be separated using an underscore, like this_is_a_long_variable.
